

Java Programming Lab (Arrays and Strings)

1. Write a Java program to read n elements into a one-dimensional array and find the sum, average, maximum, and minimum values.
2. Write a Java program to read n elements in a one-dimensional array and display the elements in reverse order and count the number of even and odd elements.
3. Write a Java program to search for a given element in a one-dimensional array and display its position(s) if found.
4. Write a Java program to read two one-dimensional arrays and merge them into a single array, then display the merged array in sorted order.
5. Write a Java program to read a matrix using a two-dimensional array and compute the sum of each row and each column.
6. Write a Java program to perform matrix addition and matrix subtraction using two-dimensional arrays.
7. Write a Java program to check whether a given matrix is symmetric using a two-dimensional array.
8. Write a Java program using a three-dimensional array to store marks of students for multiple classes and subjects and calculate total marks of each student.
9. Write a Java program to read a string and count the number of vowels, consonants, digits, and special characters.
10. Write a Java program to store multiple strings in an array and display them in alphabetical order, then find the longest string among them.
